1 Convertible: Data-Conversion Protocol

```
(require file/convertible)
```

The file/convertible library provides a protocol to mediate between providers of data in different possible formats and consumers of the formats. For example, a datatype that implements prop:convertible might be able to convert itself to a GIF or PDF stream, in which case it would produce data for 'gif-bytes or 'pdf-bytes requests.

Any symbol can be used for a conversion request, but the following should be considered standard:

- 'text a string for human-readable text
- 'gif-bytes a byte string containing a GIF image encoding
- 'png-bytes a byte string containing a PNG image encoding
- 'ps-bytes a byte string containing a PostScript document
- 'eps-bytes a byte string containing an Encapsulated PostScript document
- 'pdf-bytes a byte string containing a PDF document
- 'pdf-bytes+bounds a list containing a byte string and four numbers; the byte string contains a PDF document and the four numbers are sizing information for the PDF document, namely the width, height, ascent and descent in that order

```
prop:convertible : struct-type-property?
```

A property whose value should be a procedure of three arguments. The procedure is called when a structure with the property is passed to **convert**; the first argument to the procedure is the structure, the second argument is a symbol for the requested conversion, and the third argument is a value to return (typically #f if the conversion is not supported. The procedure's result depends on the requested conversion.

```
(convertible? v) → boolean?
 v : any/c
```

Returns #t if v supports the conversion protocol, #f otherwise.

```
(convert v request [default])
```

Requests a data conversion from v, where request indicates the type of requested data and default is the value that the converter should return if it cannot produce data in the format indicated by request.

2 gzip Compression and File Creation

```
(require file/gzip)
```

The file/gzip library provides utilities to create archive files in gzip format, or simply to compress data using the pkzip "deflate" method.

```
(gzip in-file [out-file]) → void?
  in-file : path-string?
  out-file : path-string? = (string-append in-file ".gz")
```

Compresses data to the same format as the gzip utility, writing the compressed data directly to a file. The in-file argument is the name of the file to compress. If the file named by out-file exists, it will be overwritten.

Reads the port *in* for data and compresses it to *out*, outputting the same format as the gzip utility. The *orig-filename* string is embedded in this output; *orig-filename* can be #f to omit the filename from the compressed stream. The *timestamp* number is also embedded in the output stream, as the modification date of the original file (in Unix seconds, as *file-or-directory-modify-seconds* would report on Unix).

Writes pkzip-format "deflated" data to the port *out*, compressing data from the port *in*. The data in a file created by gzip uses this format (preceded with header information).

The result is three values: the number of bytes read from in, the number of bytes written to out, and a cyclic redundancy check (CRC) value for the input.

3 gzip Decompression

```
(require file/gunzip)
```

The file/gunzip library provides utilities to decompress archive files in gzip format, or simply to decompress data using the pkzip "inflate" method.

Extracts data that was compressed using the gzip utility (or gzip function), writing the uncompressed data directly to a file. The file argument is the name of the file containing compressed data. The default output file name is the original name of the compressed file as stored in file. If a file by this name exists, it will be overwritten. If no original name is stored in the source file, "unzipped" is used as the default output file name.

The output-name-filter procedure is applied to two arguments—the default destination file name and a boolean that is #t if this name was read from file—before the destination file is created. The return value of the file is used as the actual destination file name (to be opened with the 'truncate flag of open-output-file).

If the compressed data turns out to be corrupted, the exn:fail exception is raised.

```
(gunzip-through-ports in out) → void?
  in : input-port?
  out : output-port?
```

Reads the port in for compressed data that was created using the gzip utility, writing the uncompressed data to the port out.

If the compressed data turns out to be corrupted, the exn:fail exception is raised. The unzipping process may peek further into *in* than needed to decompress the data, but it will not consume the unneeded bytes.

```
(inflate in out) → void?
  in : input-port?
  out : output-port?
```

Reads pkzip-format "deflated" data from the port *in* and writes the uncompressed ("inflated") data to the port *out*. The data in a file created by gzip uses this format (preceded with some header information).

If the compressed data turns out to be corrupted, the exn:fail exception is raised. The inflate process may peek further into *in* than needed to decompress the data, but it will not consume the unneeded bytes.

4 zip File Creation

```
(require file/zip)
```

The file/zip library provides utilities to create zip archive files, which are compatible with both Windows and Unix (including Mac OS X) unpacking. The actual compression is implemented by deflate.

```
(zip zip-file path ...) → void?
zip-file : path-string?
path : path-string?
```

Creates zip-file, which holds the complete content of all paths. The given paths are all expected to be relative path names of existing directories and files (i.e., relative to the current directory). If a nested path is provided as a path, its ancestor directories are also added to the resulting zip file, up to the current directory (using pathlist-closure). Files are packaged as usual for zip files, including permission bits for both Windows and Unix (including Mac OS X). The permission bits are determined by file-or-directory-permissions, which does not preserve the distinction between owner/group/other permissions. Also, symbolic links are always followed.

```
(zip->output paths [out]) → void?
  paths : (listof path-string?)
  out : output-port? = (current-output-port)
```

Zips each of the given paths, and packages it as a zip "file" that is written directly to out. Unlike zip, the specified paths are included as-is; if a directory is specified, its content is not automatically added, and nested directories are added without parent directories.

```
(zip-verbose) → boolean?
(zip-verbose on?) → void?
on?: any/c
```

A parameter that controls output during a zip operation. Setting this parameter to a true value causes zip to display to (current-error-port) the filename that is currently being compressed.

5 zip File Extraction

```
(require file/unzip)
```

The file/unzip library provides a function to extract items from a zip archive.

Unzips an entire zip archive from in.

For each entry in the archive, the <code>entry-reader</code> procedure is called with three arguments: the byte string representing the entry name, a boolean flag indicating whether the entry represents a directory, and an input port containing the inflated contents of the entry. The default <code>entry-reader</code> unpacks entries to the filesystem; call <code>make-filesystem-entry-reader</code> to configure aspects of the unpacking, such as the destination directory.

Creates a zip entry reader that can be used with either unzip or unzip-entry and whose behavior is to save entries to the local filesystem. Intermediate directories are always created if necessary before creating files. Directory entries are created as directories in the filesystem, and their entry contents are ignored.

If dest-path is not #f, every path in the archive is prefixed to determine the destination path of the extracted entry.

If strip-count is positive, then strip-count path elements are removed from the entry path from the archive (before prefixing the path with dest-path); if the item's path contains strip-count elements, then it is not extracted.

If exists is 'skip and the file for an entry already exists, then the entry is skipped. Otherwise, exists is passed on to open-output-file for writing the entry's inflated content.

```
(read-zip-directory in) → zip-directory?
in : (or/c path-string? input-port?)
```

Reads the central directory of a zip file and generates a *zip directory* representing the zip file's contents. If *in* is an input port, it must support position setting via file-position.

This procedure performs limited I/O: it reads the list of entries from the zip file, but it does not inflate any of their contents.

```
(zip-directory? v) \rightarrow boolean? v : any/c
```

Returns #t if v is a zip directory, #f otherwise.

```
(zip-directory-entries zipdir) \rightarrow (listof bytes?) zipdir : zip-directory?
```

Extracts the list of entries for a zip archive.

```
(zip-directory-contains? zipdir name) → boolean?
zipdir : zip-directory?
name : (or/c bytes? path-string?)
```

Determines whether the given entry name occurs in the given zip directory. If name is not a byte string, it is converted using path->zip-path.

Directory entries match with or without trailing slashes.

Determines whether the given name is included anywhere in the given zip directory as a filesystem directory, either as an entry itself or as the containing directory of other entries. If name is not a byte string, it is converted using path->zip-path.

Unzips a single entry from a zip archive based on a previously read zip directory, zipdir, from read-zip-directory. If in is an input port, it must support position setting via file-position.

The *entry* parameter is a byte string whose name must be found in the zip file's central directory. If *entry* is not a byte string, it is converted using path->zip-path.

The read-entry argument is used to read the contents of the zip entry in the same way as for unzip.

If entry is not in zipdir, an exn:fail:unzip:no-such-entry exception is raised.

```
(path->zip-path path) → bytes?
  path : path-string?
```

Converts a file name potentially containing path separators in the current platform's format to use path separators recognized by the zip file format: \(\nslant \).

```
(struct exn:fail:unzip:no-such-entry exn:fail (entry)
         #:extra-constructor-name
          make-exn:fail:unzip:no-such-entry)
entry: bytes?
```

Raised when a requested entry cannot be found in a zip archive. The entry field is a byte string representing the requested entry name.

6 tar File Creation

```
(require file/tar)
```

The file/tar library provides utilities to create archive files in USTAR format, like the archive that the Unix utility pax generates. The USTAR format imposes limits on path lengths. The resulting archives contain only directories and files (symbolic links are followed), and owner information is not preserved; the owner that is stored in the archive is always "root."

```
(tar tar-file path ...) → exact-nonnegative-integer?
  tar-file : path-string?
  path : path-string?
```

Creates tar-file, which holds the complete content of all paths. The given paths are all expected to be relative path names of existing directories and files (i.e., relative to the current directory). If a nested path is provided as a path, its ancestor directories are also added to the resulting tar file, up to the current directory (using pathlist-closure).

```
(tar->output paths [out]) → exact-nonnegative-integer?
  paths : (listof path?)
  out : output-port? = (current-output-port)
```

Packages each of the given paths in a tar format archive that is written directly to the out. The specified paths are included as-is; if a directory is specified, its content is not automatically added, and nested directories are added without parent directories.

```
(tar-gzip tar-file paths ...) → void?
  tar-file : path-string?
  paths : path-string?
```

Like tar, but compresses the resulting file with gzip.

7 tar File Extraction

```
(require file/untar)
```

The file/untar library provides a function to extract items from a TAR/USTAR archive.

Extracts TAR/USTAR content from in.

If dest-path is not #f, every path in the archive is prefixed to determine the destination path of the extracted item.

If strip-count is positive, then strip-count path elements are removed from the item path from the archive (before prefixing the path with dest-path); if the item's path contains strip-count elements, then it is not extracted.

For each item in the archive, filter-proc is applied to

- the item's path as it appears in the archive;
- a destination path that is based on the path in the archive, strip-count, and dest-path—which can be #f if the item's path does not have strip-count or more elements;
- a symbol representing the item's type—'file, 'dir, 'link, 'hard-link, 'character-special, 'block-special, 'fifo, 'contiguous-file, 'extended-header, 'extended-header-for-next, or 'unknown—where only 'file, 'dir, or 'link can be unpacked by untar;
- an exact integer representing the item's size;
- a target path for a 'link type or #f for any other type;
- an integer representing the item's modification date; and

• an integer representing the item's permissions

If the result of filter-proc is #f, then the item is not unpacked.

8 tar+gzip File Extraction

```
(require file/untgz)
```

The file/untgz library provides a function to extract items from a possible gzipped TAR/USTAR archive.

The same as untar, but if in is in gzip form, it is gunzipped as it is unpacked.

9 MD5 Message Digest

```
(require file/md5)

(md5 in [hex-encode?]) → bytes?
  in : (or/c input-port? bytes? string?)
  hex-encode? : boolean? = #t
```

If hex-encode? is #t, produces a byte string containing 32 hexadecimal digits (lowercase) that is the MD5 hash of the given input stream or byte string. Otherwise produces the 16 byte long byte string that is the MD5 hash of the given input stream or byte string.

Examples:

```
> (md5 #"abc")
#"900150983cd24fb0d6963f7d28e17f72"
> (md5 #"abc" #f)
#"\220\1P\230<\3220\260\326\226?}(\341\177r"</pre>
```

10 SHA1 Message Digest

```
(require file/sha1)
```

See openssl/sha1 for a faster implementation.

```
(\operatorname{sha1}\ in) \to \operatorname{string}?
in: \operatorname{input-port}
```

Returns a 40-character string that represents the SHA-1 hash (in hexadecimal notation) of the content from *in*, consuming all of the input from *in* until an end-of-file.

The sha1 function composes bytes->hex-string with sha1-bytes.

Example:

```
> (sha1 (open-input-bytes #"abc"))
"a9993e364706816aba3e25717850c26c9cd0d89d"

(sha1-bytes in) → bytes?
  in : input-port
```

Returns a 20-byte byte string that represents the SHA-1 hash of the content from *in*, consuming all of the input from *in* until an end-of-file.

Example:

```
> (sha1-bytes (open-input-bytes #"abc"))
#"\251\231>6G\6\201j\272>%qxP\3021\234\320\330\235"

(bytes->hex-string bstr) → string?
   bstr : bytes?
```

Converts the given byte string to a string representation, where each byte in *bstr* is converted to its two-digit hexadecimal representation in the resulting string.

11 GIF File Writing

```
(require file/gif)
```

The file/gif library provides functions for writing GIF files to a stream, including GIF files with multiple images and controls (such as animated GIFs).

A GIF stream is created by gif-start, and then individual images are written with gif-add-image. Optionally, gif-add-control inserts instructions for rendering the images. The gif-end function ends the GIF stream.

A GIF stream can be in any one of the following states:

- 'init: no images or controls have been added to the stream
- 'image-or-control: another image or control can be written
- 'image: another image can be written (but not a control, since a control was written)
- 'done : nothing more can be added

```
(gif-stream? v) \rightarrow boolean? v : any/c
```

Returns #t if v is a GIF stream created by gif-write, #f otherwise.

```
(image-ready-gif-stream? v) \rightarrow boolean? v : any/c
```

Returns #t if v is a GIF stream that is not in 'done mode, #f otherwise.

```
(image-or-control-ready-gif-stream? v) \rightarrow boolean? v : any/c
```

Returns #t if v is a GIF stream that is in 'init or 'image-or-control mode, #f otherwise.

```
(\text{empty-gif-stream}? \ v) \rightarrow \text{boolean}?
v : \text{any/c}
```

Returns #t if v is a GIF stream that in 'init mode, #f otherwise.

```
(gif-colormap? v) \rightarrow boolean? v : any/c
```

Returns #t if v represets a colormap, #f otherwise. A colormap is a list whose size is a power of 2 between 2^1 and 2^8 , and whose elements are vectors of size 3 containing colors (i.e., exact integers between 0 and 255 inclusive).

```
(color? v) \rightarrow boolean?
 v : any/c
```

The same as byte?.

```
(dimension? v) \rightarrow boolean? v : any/c
```

Returns #t if v is an exact integer between 0 and 65535 inclusive, #f otherwise.

```
(gif\text{-state } stream) \rightarrow symbol?
stream : gif\text{-stream}?
```

Returns the state of stream.

```
(gif-start out w h bg-color cmap) → gif-stream?
  out : output-port?
  w : dimension?
  h : dimension?
  bg-color : color?
  cmap : (or/c gif-colormap? #f)
```

Writes the start of a GIF file to the given output port, and returns a GIF stream that adds to the output port.

The width and height determine a virtual space for the overall GIF image. Individual images added to the GIF stream must fit within this virtual space. The space is initialized by the given background color.

Finally, the default meaning of color numbers (such as the background color) is determined by the given colormap, but individual images within the GIF file can have their own colormaps.

A global colormap need not be supplied, in which case a colormap must be supplied for each image. Beware that the bg-color is ill-defined if a global colormap is not provided.

```
(gif-add-image stream
               left
                top
                width
               height
                interlaced?
                cmap
                bstr)
                            \rightarrow void?
 stream : image-ready-gif-stream?
 left : dimension?
 top : dimension?
 width : dimension?
 height : dimension?
 interlaced? : any/c
 cmap : (or/c gif-colormap? #f)
 bstr : bytes?
```

Writes an image to the given GIF stream. The left, top, width, and height values specify the location and size of the image within the overall GIF image's virtual space.

If *interlaced?* is true, then *bstr* should provide bytes ininterlaced order instead of top-to-bottom order. Interlaced order is:

- every 8th row, starting with 0
- every 8th row, starting with 4
- every 4th row, starting with 2
- every 2nd row, starting with 1

If a global color is provided with gif-start, a #f value can be provided for cmap.

The *bstr* argument specifies the pixel content of the image. Each byte specifies a color (i.e., an index in the colormap). Each row is provided left-to-right, and the rows provided either top-to-bottom or in interlaced order (see above). If the image is prefixed with a control that specifies an transparent index (see gif-add-control), then the corresponding "color" doesn't draw into the overall GIF image.

An exception is raised if any byte value in *bstr* is larger than the colormap's length, if the *bstr* length is not *width* times *height*, or if the *top*, *left*, *width*, and *height* dimensions specify a region beyond the overall GIF image's virtual space.

Writes an image-control command to a GIF stream. Such a control must appear just before an image, and it applies to the following image.

The GIF image model involves processing images one by one, placing each image into the specified position within the overall image's virtual space. An image-control command can specify a delay before an image is added (to create animated GIFs), and it also specifies how the image should be kept or removed from the overall image before proceeding to the next one (also for GIF animation).

The disposal argument specifies how to proceed:

- 'any : doesn't matter (perhaps because the next image completely overwrites the current one)
- 'keep: leave the image in place
- 'restore-bg : replace the image with the background color
- 'restore-prev: restore the overall image content to the content before the image is added

If wait-for-input? is true, then the display program may wait for some cue from the user (perhaps a mouse click) before adding the image.

The delay argument specifies a delay in 1/100s of a second.

If the *transparent* argument is a color, then it determines an index that is used to represent transparent pixels in the follow image (as opposed to the color specified by the colormap for the index).

An exception is raised if a control is already added to stream without a corresponding image.

```
(gif-add-loop-control stream iteration) → void?
  stream : empty-gif-stream?
  iteration : dimension?
```

Writes a control command to a GIF stream for which no images or other commands have already been written. The command causes the animating sequence of images in the GIF to be repeated 'iteration-dimension' times, where 0 can be used to mean "infinity."

An exception is raise if some control or image has been added to the stream already.

```
(gif-add-comment stream bstr) → void?
  stream : image-or-control-ready-gif-stream?
  bstr : bytes?
```

Adds a generic comment to the GIF stream.

An exception is raised if an image-control command was just written to the stream (so that an image is required next).

```
(gif-end stream) \rightarrow void?

stream : image-or-control-ready-gif-stream?
```

Finishes writing a GIF file. The GIF stream's output port is not automatically closed.

An exception is raised if an image-control command was just written to the stream (so that an image is required next).

Each image in a GIF stream is limited to 256 colors, including the transparent "color," if any. The quantize function converts a 24-bit image (plus alpha channel) into an indexed-color image, reducing the number of colors if necessary.

Given a set of pixels expressed in ARGB format (i.e., each four bytes is a set of values for one pixel: alpha, red, blue, and green), quantize produces produces

- bytes for the image (i.e., a array of colors, expressed as a byte string)
- a colormap
- either #f or a color index for the transparent "color"

The conversion treats alpha values less than 128 as transparent pixels, and other alpha values as solid.

The quantization process uses Octrees [Gervautz1990] to construct an adaptive palette for all (non-transparent) colors in the image. This implementation is based on an article by Dean Clark [Clark1996].

To convert a collection of images all with the same quantization, simply append them for the input of a single call of quantize, and then break apart the result bytes.

12 ICO File Reading and Writing

```
(require file/ico)
```

The file/ico library provides functions for reading and writing ".ico" files, which contain one or more icons. Each icon is up to 256 by 256 pixels, has a particular depth (i.e., bits per pixel used to represent a color), and mask (i.e., whether a pixel is shown, except that the mask may be ignored for 32-bit icons that have an alpha value per pixel).

```
(ico? v) \rightarrow boolean?
v : any/c
```

Returns #t if v represents an icon, #f otherwise.

```
(ico-width ico) → (integer-in 1 256)
  ico : ico?
(ico-height ico) → (integer-in 1 256)
  ico : ico?
(ico-depth ico) → (one-of/c 1 2 4 8 16 24 32)
  ico : ico?
```

Returns the width or height of an icon in pixels, or the depth in bits per pixel.

```
(read-icos src) → (listof ico?)
src : (or/c path-string? input-port?)
```

Parses src as an ".ico" to extract a list of icons.

```
(read-icos-from-exe\ src) \rightarrow (listof\ ico?)
src: (or/c\ path-string?\ input-port?)
```

Parses src as an ".exe" to extract the list of icons that represent the Windows executable.

Writes each icon in *icos* to *dest* as an ".ico" file. If *dest* is not an output port, *exists* is passed on to open-output-file to open *dest* for writing.

```
(replace-icos icos dest) → void?
  icos : (listof ico?)
  dest : (or/c path-string? output-port?)
```

Writes icons in *icos* to replace icons in *dest* as an Windows executable. Only existing icon sizes and depths in the executable are replaced, and best matches for the existing sizes and depth are drawn from *icos* (adjusting the scale and depth f a best match as necessary).

```
(ico->argb ico) → bytes?
 ico : ico?
```

Converts an icon to an ARGB byte string, which has the icon's pixels in left-to-right, top-to-bottom order, with four bytes (alpha, red, green, and blue channels) for each pixel.

```
(argb->ico width height bstr [#:depth depth]) → ico?
width : (integer-in 1 256)
height : (integer-in 1 256)
bstr : bytes?
depth : (one-of/c 1 2 4 8 24 32) = 32
```

Converts an ARGB byte string (in the same format as from ico->argb) to an icon of the given width, height, and depth.

The bstr argument must have a length (* 4 width height), and (* width depth) must be a multiple of 8.

13 Windows Registry

Gets a value from the Windows registry or an ".ini" file. For backward compatibility, the result is #f for platforms other than Windows. The registry is read when file is #f and when section is "HKEY_CLASSES_ROOT", "HKEY_CURRENT_CONFIG", "HKEY_CURRENT_USER", "HKEY_LOCAL_MACHINE", or "HKEY_USERS". When file is #f and section is not one of the special registry strings, then (build-path (find-system-path 'home-dir) "mred.ini") is read.

The resource value is keyed on the combination of section and entry. The result is #f if no value is found for the specified section and entry. If value-box is a box, then the result is #t if a value is found, and the box is filled with the value; when value-box is #f, the result is the found value.

The type argument determines how a value in the resource is converted to a Racket value. If value-box is a box, then the default type is derived from the initial box content, otherwise the default type is 'string.

Registry values of any format can be extracted. Values using the registry format REG_SZ are treated as strings, and values with the format REG_DWORD are treated as 32-bit signed integers. All other formats are treated as raw bytes. Data from the registry is converted to the requested type as follows:

- A REG_SZ registry value is converted to an integer using string->number (using 0 if the result is not an exact integer), and it is converted to bytes using string->bytes/utf-8.
- A REG_DWORD registry value is converted to a string or byte string via number->string and (for byte strings) string->bytes/utf-8.
- Any other kind of registry value is converted to a string or integer using bytes->string/utf-8 and (for integers) string->number.

Resources from ".ini" files are always strings, and are converted like REG_SZ registry values.

To get the "default" value for a registry entry, use a trailing backslash. For example, the following expression gets a command line for starting a browser:

Write a value to the Windows registry or an ".ini" file. For backward compatibility, the result is #f for platforms other than Windows. The registry is written when file is #f and when section is "HKEY_CLASSES_ROOT", "HKEY_CURRENT_CONFIG", "HKEY_CURRENT_USER", "HKEY_LOCAL_MACHINE", or "HKEY_USERS". When file is #f and section is not one of the special registry strings, then (build-path (find-system-path 'home-dir) "mred.ini") is written.

The resource value is keyed on the combination of section and entry. If create-key? is false when writing to the registry, the resource entry must already exist, otherwise the write fails. The result is #f if the write fails or #t if it succeeds.

The type argument determines the format of the value written to the registry: 'string writes using the REG_SZ format, 'bytes writes using the REG_BINARY format, and 'dword writes using the REG_DWORD format. Any kind of value can be converted for any kind of type using the inverse of the conversions for get-resource.

When writing to an ".ini" file, the format is always a string, independent of type.

Bibliography
