Unstable Redex: May Change Without Warning

Version 6.2

June 19, 2015

This library is *unstable*; compatibility will not be maintained. See *Unstable: May Change Without Warning* for more information.

```
(require unstable/gui/redex)        package: unstable-redex
```

This library provides functions to help typesetting for `redex` models. The following example program provides an overview of the features:

```
> (define-language ZF
    [e empty
       (Set e)
       (Union e_1 e_2)
       (Powerset e)
       ZZ
       variable-not-otherwise-mentioned]
    [formula (same? e_1 e_2)
             (in? e_1 e_2)
             true
             false
             (implies formula_1 formula_2)])
```

By default, Redex models are typeset as S-expressions with some basic styling that distinguishes literals from nonterminal names, handles subscripting, etc.

```
> (language->pict ZF)
```

$$e ::= \text{empty}$$
$$| \; (\text{Set } e)$$
$$| \; (\text{Union } e_1 \; e_2)$$
$$| \; (\text{Powerset } e)$$
$$| \; ZZ$$
$$| \; \textit{variable-not-otherwise-mentioned}$$
$$\textit{formula} ::= (\text{same? } e_1 \; e_2)$$
$$| \; (\text{in? } e_1 \; e_2)$$
$$| \; \text{true}$$
$$| \; \text{false}$$
$$| \; (\text{implies } \textit{formula}_1 \; \textit{formula}_2)$$

```
> (term->pict ZF (in? x (Set 1 2 3 ...)))
(in? x (Set 1 2 3 …))
```

This library provides helper functions for creating and using rewriters that transform the S-expression model terms into other notations.

```
> (add-atomic-rewriters!
   'empty "∅"
   'formula "φ"
   'ZZ (text "Z" '(bold . modern) (default-font-size))
   'variable-not-otherwise-mentioned
       (lambda () (text "x, y, z, ..." (literal-style) (default-
font-size)))
   'true (lambda () (text "true" '(caps . modern) (default-font-
size)))
   'false (lambda () (text "false" '(caps . modern) (default-font-
size)))))

> (add-compound-rewriters!
   'same? (binary-rw " = ")
   'in? (binary-rw " ∈ ")
   'Set (bracket-rw 'curly)
   'Powerset (function-rw "P")
   'Union (binary-rw "∪")
   'implies (binary-rw " ⇒ " #:parenthesize-left '(implies)))

> (with-rewriters
    (lambda ()
      (language->pict ZF)))
```

$e ::= \varnothing$
$\quad | \{e\}$
$\quad | e_1 \cup e_2$
$\quad | \mathrm{P}(e)$
$\quad | \mathbf{Z}$
$\quad | x, y, z, ...$
$\varphi ::= e_1 = e_2$
$\quad | e_1 \in e_2$
$\quad | \text{TRUE}$
$\quad | \text{FALSE}$
$\quad | \varphi_1 \Rightarrow \varphi_2$

```
> (with-rewriters
    (lambda ()
      (render-term ZF (in? x (Set 1 2 3 ...)))))
```
$x \in \{1, 2, 3, ...\}$

```
(with-rewriters proc) → any
  proc : (-> any)
```

Calls `proc` with the rewriters of `current-atomic-rewriters`, `current-compound-rewriters`, and `current-unquote-rewriters`.

```
(current-atomic-rewriters)
 → (let ([atomic-rewriter/c
           (or/c string? pict?
                 (-> (or/c string? pict?)))])
      (plistof symbol? atomic-rewriter/c))
(current-atomic-rewriters rewriters) → void?
  rewriters : (let ([atomic-rewriter/c
                      (or/c string? pict?
                            (-> (or/c string? pict?)))])
                (plistof symbol? atomic-rewriter/c))
```

Parameter of atomic rewriters (as in `with-atomic-rewriter`) used by `with-rewriters`.

```
(current-compound-rewriters)
 → (plistof symbol? compound-rewriter/c)
(current-compound-rewriters rewriters) → void?
  rewriters : (plistof symbol? compound-rewriter/c)
```

Parameter of compound rewriters (as in `with-compound-rewriter`) used by `with-rewriters`.

```
(current-unquote-rewriters)
 → (plistof (-> lw? any/c) (-> lw? lw?))
(current-unquote-rewriters rewriters) → void?
  rewriters : (plistof (-> lw? any/c) (-> lw? lw?))
```

Parameter of unquote rewriters (as in `with-unquote-rewriter`) used by `with-rewriters`.

```
(add-atomic-rewriters! rewriters) → void?
  rewriters : (let ([atomic-rewriter/c
                      (or/c string? pict?
                            (-> (or/c string? pict?)))])
               (plistof symbol? atomic-rewriter/c))
(add-compound-rewriters! rewriters) → void?
  rewriters : (plistof symbol? compound-rewriter/c)
(add-unquote-rewriters! rewriters) → void?
  rewriters : (plistof (-> lw? any/c) (-> lw? lw?))
```

Add rewriters to the `current-atomic-rewriters`, `current-compound-rewriters`, or `current-unquote-rewriters`, respectively.

```
(plistof key/c value/c) → contract?
  key/c : contract?
  value/c : contract?
```

Contract for even-length lists of alternating *key/c* and *value/c* values.

Equivalent to

```
  (letrec ([ctc
              (recursive-contract
               (or/c '()
                     (cons/c key/c (cons/c value/c ctc))))])
    ctc)
```

```
compound-rewriter/c : contract?
```

Contract for compound rewriters, which take a list of `lw` structs and returns a list of `lw`s, `pict`s, or strings.

Equivalent to

```
 (-> (listof lw?)
     (listof (or/c lw? pict? string?)))
```

```
(binary-rw  operator
            [#:parenthesize-arg parenthesize-arg
             #:parenthesize-left parenthesize-left
             #:parenthesize-right parenthesize-right])
 → compound-rewriter/c
  operator : (or/c string? pict? (-> (or/c string? pict?)))
  parenthesize-arg : (or/c #t #f (listof symbol?) (-> lw? any/c))
                   = #f
  parenthesize-left : (or/c #t #f (listof symbol?) (-> lw? any/c))
                    = parenthesize-arg
  parenthesize-right : (or/c #t #f (listof symbol?) (-> lw? any/c))
                     = parenthesize-arg
```

Typesets `(sym  term1  term2)` using `operator` as a binary operator between `term1` and `term2`.

Examples:

```
> (add-compound-rewriters!
    'plus (binary-rw " + "))

> (with-rewriters
     (lambda ()
       (term->pict ZF (plus 1 2))))
1 + 2
```

Redex terms may become ambiguous when typeset. To avoid ambiguity, use `#:parenthesize-arg` to direct when arguments should be parenthesized. If `parenthesize-arg` is `#t`, then arguments are always parenthesized; if it is `#f`, never; if it is a list of symbols, then an argument is parenthesized only if the argument is a term starting with a symbol in the list; if it is a procedure, then the argument is parenthesized if the procedure applied to the argument's `lw` struct returns a true value.

```
> (add-compound-rewriters!
    'times (binary-rw " × "))

> (with-rewriters
     (lambda ()
       (term->pict ZF (times (plus 1 2) 3))))
1 + 2 × 3
> (add-compound-rewriters!
    'times (binary-rw " × " #:parenthesize-arg '(plus)))
```

```
> (with-rewriters
     (lambda ()
       (term->pict ZF (times (plus 1 2) 3))))
```
(1 + 2) × 3

The parenthesization rules for left and right arguments can be supplied separately through `#:parenthesize-left` and `#:parenthesize-right`, for example to create left-associated or right-associated operators:

```
> (add-compound-rewriters!
     'arrow (binary-rw " → " #:parenthesize-left '(arrow)))

> (with-rewriters
     (lambda ()
       (term->pict ZF (arrow (arrow A B) (arrow C D)))))
```
(A → B) → C → D

```
(prefix-rw  prefix
            [#:parenthesize-arg parenthesize-arg])
 → compound-rewriter/c
  prefix : (or/c string? pict? (-> (or/c string? pict?)))
  parenthesize-arg : (or/c #f #t (listof symbol?) (-> lw? any/c))
                   = #f
```

Typesets (*sym* *term*) by placing *prefix* before *term*.

Examples:

```
> (add-compound-rewriters!
     'not (prefix-rw "¬ "))

> (with-rewriters
     (lambda ()
       (term->pict ZF (not (in? x empty)))))
```
¬ x ∈ ∅

```
(postfix-rw  postfix
             [#:parenthesize-arg parenthesize-arg])
 → compound-rewriter/c
  postfix : (or/c string? pict? (-> (or/c string? pict?)))
  parenthesize-arg : (or/c #f #t (listof symbol?) (-> lw? any/c))
                   = #f
```

Typesets (*sym* *term*) by placing *postfix* after *term*.

Examples:

```
> (add-compound-rewriters!
    'nonempty (postfix-rw " is nonempty"))

> (with-rewriters
    (lambda ()
      (term->pict ZF (nonempty (Set x)))))
{x} is nonempty
```

(function-rw *function*) → compound-rewriter/c
  function : (or/c string? pict? (-> (or/c string? pict?)))

Typesets (*sym term* ...) by placing *function* before the parenthesized, comma-separated list of *term*s.

Examples:

```
> (add-compound-rewriters!
    'f (function-rw "f")
    'max (function-rw (text "max" '(bold . modern) (default-font-
size))))

> (with-rewriters
    (lambda ()
      (term->pict ZF (max 1 2 (f 3)))))
max(1, 2, f(3))
```

(only-first-rw) → compound-rewriter/c

Typesets (*sym term1 term2* ...) as *term1*. Useful for hiding parameters that are necessary for defining the semantics but can be glossed over in its explanation, such as state parameters used for generating unique names.

Examples:

```
> (add-compound-rewriters!
    'First (only-first-rw))

> (with-rewriters
    (lambda ()
      (term->pict ZF [First (in? x y) counter])))
x ∈ y
```

(splice-rw) → compound-rewriter/c

Typesets (*sym* *term* ...) by rendering the *term*s side-by-side.

```
(constant-rw constant) → compound-rewriter/c
  constant : (or/c string? pict? (-> (or/c string? pict?)))
```

Typesets (*sym* *term* ...) as *constant*.

```
(bracket-rw brackets [#:comma? comma?]) → compound-rewriter/c
  brackets : (or/c 'round 'square 'curly 'angle
                   (list (or/c string? pict?)
                         (or/c string? pict?)))
  comma? : any/c = #t
```

Typesets (*sym* *term* ...) by surrounding the comma-separated (or space-separated, if *comma?* is false) sequence of *term*s with brackets. If *brackets* is a list, the first element is the left bracket and the second is the right bracket; `'round` is equivalent to `'("(" ")")`; `'square` is equivalent to `'("[" "]")`; `'curly` is equivalent to `'("{" "}")`; and `'angle` is equivalent to `'("⟨" "⟩")`.

Examples:

```
> (add-compound-rewriters!
    'Tuple (bracket-rw 'angle))

> (with-rewriters
    (lambda ()
      (term->pict ZF (Tuple 1 2 3))))
```
⟨1, 2, 3⟩

```
(set-cons-rw) → compound-rewriter/c
```

Rewriter that typesets (*sym* *elem-term* *set-term*) as the union of the singleton set containing *elem-term* with the set *set-term*.

Examples:

```
> (add-compound-rewriters!
    'set-cons (set-cons-rw))

> (with-rewriters
    (lambda ()
      (term->pict ZF (set-cons x S))))
```
{x}∪S
